

# CLEAN POWER, CLEAR SAVINGS

## NEW HAMPSHIRE

---

**The EPA Clean Power Plan Will Cut New Hampshire  
Electricity Bills by 10.3 to 11.5 Percent by 2030**

## **Acknowledgments**

This report was written by David Arkush, managing director of Public Citizen's Climate Program. Starla Yeh and Kevin Steinberger of the Natural Resources Defense Council provided helpful input and reviews of the methodology.

## **About Public Citizen**

Public Citizen is a national non-profit organization with more than 400,000 members and supporters. We represent consumer interests through lobbying, litigation, administrative advocacy, research, and public education on a broad range of issues including consumer rights in the marketplace, product safety, financial regulation, worker safety, safe and affordable health care, campaign finance reform and government ethics, fair trade, climate change, and corporate and government accountability.

## Introduction

This summer, the Environmental Protection Agency (EPA) expects to finalize its first-ever rule to curb carbon pollution from existing power plants, known as the Clean Power Plan.<sup>1</sup> This report finds that the EPA rule should lower New Hampshire electricity bills substantially, and that the state can and should do even better.

Detractors often argue that EPA proposal will raise electricity rates. That claim focuses on the wrong question from the standpoint of electricity customers. For a consumer or business focused on costs, the key question is what effect the Clean Power Plan will have on what they actually pay, which means electricity *bills*. Although the EPA projects that the retail price of electricity will rise modestly under the Clean Power Plan compared to a business-as-usual scenario, it also expects the rule to spur improvements in energy efficiency so that people use less electricity. The net result is that electricity bills will fall, not rise.

The EPA estimates that, in addition to mitigating climate change and boosting public health, the proposed Clean Power Plan will lower electricity bills nationwide by 8.4 percent by 2030 compared to a business-as-usual scenario.<sup>2</sup> The agency did not conduct a state-by-state analysis of bill impacts. For this report, Public Citizen analyzed data from the EPA and the U.S. Energy Information Administration (EIA) to project the Clean Power Plan's effect on electricity bills in New Hampshire. We find that by 2030, electricity bills will be 10.3 to 11.5 percent lower under the Clean Power Plan, saving the average New Hampshire household \$122 to \$136 annually. Moreover, these numbers are likely underestimates. New Hampshire can and should do even better. The Clean Power Plan presents a great opportunity not just to fight climate change, but to lower electricity costs for consumers.

One important caveat to this report's analysis is that actual outcomes will depend on New Hampshire's policy choices. State officials will decide how to comply with the Clean Power Plan, and they can adopt policies that are better or worse for New Hampshire's electricity customers. Energy efficiency should feature prominently in New Hampshire's compliance plan, as it is the lowest-cost way to reduce carbon emissions. It also happens to save consumers and businesses a great deal of money on their electricity bills.

To get the most benefit, the state should get a head start on ramping up its annual energy efficiency savings. New Hampshire electricity bills will rise briefly under the Clean Power Plan before they decline. The drop in costs will more than offset the initial increase, but state policymakers can mitigate the initial increase by adopting strong energy efficiency policies now, rather than waiting until later.

## The Clean Power Plan Can Lower Electricity Bills in New Hampshire

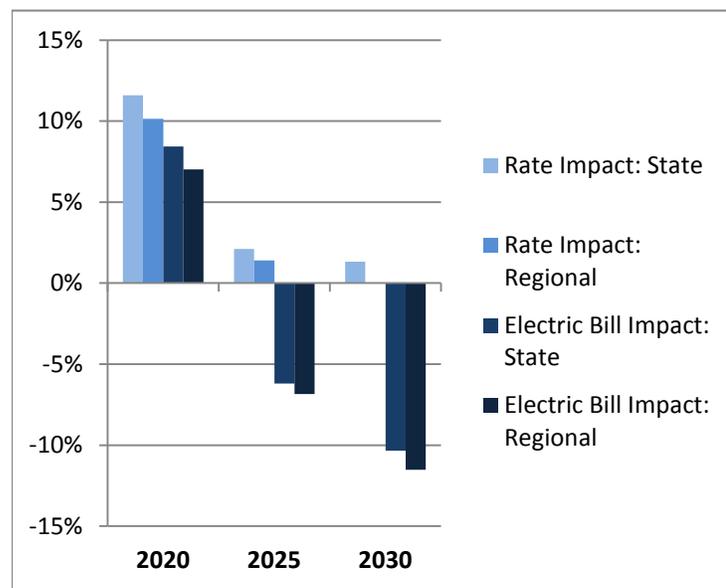

The proposed Clean Power Plan aims to cut carbon pollution from power plants by 30 percent from 2005 levels by 2030. Under the plan, the EPA will set a carbon-reduction target for each state, and

then states can decide how to meet their targets.<sup>3</sup> They can comply individually or in regional groups, and they can use a mix of different strategies, like improving the efficiency of existing coal-fired power plants, shifting some electricity generation from coal to natural gas plants, shifting to renewables or nuclear generation and using energy efficiency to reduce electricity consumption. They can also implement carbon caps or carbon taxes. The Regional Greenhouse Gas Initiative (RGGI) in which New Hampshire participates will likely be a key component of its member states' compliance plans. Energy efficiency should also play a major role, as it is the lowest-cost and most effective strategy for reducing carbon pollution by a wide margin.

Improving energy efficiency means using less electricity to do the same or more work. For example, better insulated homes require less power to heat and cool. There are many other ways to improve efficiency, ranging from switching to more efficient appliances and light bulbs to using combined heat and power (CHP) systems in industrial processes to generate electricity and usable heat in a combined system rather than independently.<sup>4</sup> Efficiency gains are usually so inexpensive that they pay for themselves quickly in reduced electricity costs. A 2014 study by the American Council for an Energy-Efficient Economy (ACEEE) found that energy efficiency programs run by utilities return \$1.41 to \$4 for every dollar spent.<sup>5</sup> For this reason, even if the retail price of electricity increases modestly under the Clean Power Plan, households and businesses will use substantially less electricity due to efficiency measures, and their bills will still decline.

Figure 1 illustrates the projected retail electricity rates and total electricity bills in New Hampshire under the Clean Power Plan, expressed as percentage changes from a business-as-usual baseline. The EPA's data suggests that the price of electricity will rise initially under the Clean Power Plan but soon fall back toward business-as-usual levels. If New Hampshire complies individually, then retail rates will be 11.6 percent higher than business-as-usual in 2020, then drop to just 2.1 percent higher in 2025 and 1.3 percent higher in 2030.<sup>6</sup> If New Hampshire complies in a regional group—as is expected, given its ongoing participation in RGGI—then the EPA's data suggests that the retail price of electricity will be 10.1 percent higher than business-as-usual in 2020, just 1.4 percent higher in 2025 and no higher in 2030.<sup>7</sup> In either case, our analysis of EPA data suggests that electricity *consumption* in New Hampshire will decline by 2.8 percent in 2020, 8.1 percent in 2025, and 11.5 percent in 2030.<sup>8</sup>

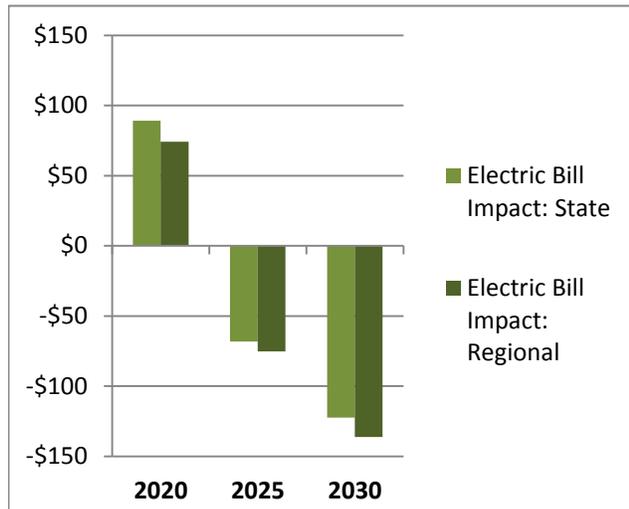

**Figure 1: Estimated CPP Impacts on Retail Rates and Total Electricity Bills in New Hampshire**

The net effect is that electricity bills will rise in 2020 by 7 to 8.4 percent—thanks to efficiency measures they will not rise as much as rates—and then decline more steeply going forward. In 2025, they will be 6.2 to 6.8 percent lower than business as usual. By 2030, electricity bills will be 10.3 to 11.5 percent lower than they would be in the absence of the Clean Power Plan.<sup>9</sup>

Figures 2(a) and 2(b) illustrate the effects of these changes on annual household expenditures, expressed in dollars. We estimate that the average household will see annual electricity bills rise by \$74 to \$89 in 2020, then decline by \$68 to \$75 in 2025 and \$122 to \$136 in 2030 compared to business-as-usual.<sup>10</sup> In other words, the typical household would pay \$1,182 for electricity in 2030 without the Clean Power Plan, but would pay \$1,046 to \$1,060 under the rule.<sup>11</sup>

**Figure 2(a): Projected Change in Annual Household Electric Bills in New Hampshire Under the CPP**

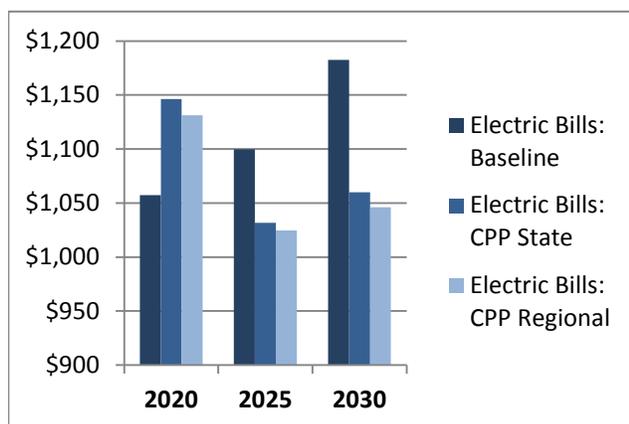

### **New Hampshire Can and Should Save More Than This Analysis Indicates**

The estimated cost reductions in this report are likely understated. This analysis is based on a compliance path that the EPA proposed for New Hampshire in the Clean Power Plan, but the state has the flexibility and capability to use substantially more efficiency than the EPA envisions. The agency's plan omits entire categories of efficiency measures that states can use, such as building codes and appliance standards.<sup>12</sup> It also assumes that states will ramp up their electricity savings rates relatively slowly—and that no state will exceed 1.5 percent annual savings even though eleven states have already set higher targets.<sup>13</sup>

New Hampshire could exceed the savings projected here, as well as mitigate the 2020 cost increase, by improving more quickly and increasing the savings rate of its efficiency programs by more than the EPA's compliance path contemplates. The EPA envisioned that states would make no progress on efficiency from 2012 to 2017 but then starting in 2018 would increase their savings rate by 0.2 percent per year until they reach a target of 1.5 percent annual savings. The agency also expressly contemplated—and sought comment on—a savings rate of 0.25 percent and a maximum

**Figure 2(b): Projected Annual Household Electric Bills in New Hampshire Under the CPP and Business-as-Usual**

target of 2 percent.<sup>14</sup> If New Hampshire starts in 2017 and increases its savings at the faster rate of 0.25 percent, it would save consumers an additional \$14 in 2020 and \$6 in 2030. If also increases its maximum target to 2.0 percent, it could help consumers save an additional \$42 in 2030.<sup>15</sup>

A recent ACEEE analysis shows a more comprehensive way New Hampshire could improve on efficiency. It finds that the state could enact a broader set of energy efficiency policies that by 2030 would save electricity customers \$500 million in 2030 alone,<sup>16</sup> as they would use 1,916 fewer gigawatt hours of electricity.<sup>17</sup> This scenario involves a 1.5 percent savings target, like EPA's, but it adds building codes, combined heat and power, and energy efficiency standards for five products.<sup>18</sup>

A second reason why this report likely underestimates the potential savings under the Clean Power Plan is that it relies on EPA's excessively high estimates of the cost of efficiency programs. The agency starts its analysis by treating efficiency measures as 60 to 100 percent more expensive than the evidence indicates, using in the EPA's own words, a "conservative" cost estimate for efficiency programs that is higher than the costs indicated by the "up-to-date, more comprehensive results" from "newer" studies.<sup>19</sup> Then the agency boosts the costs further by assuming that they escalate dramatically as the rate of energy efficiency savings increases.<sup>20</sup> This assumption is no more obvious than the opposite one, that efficiency becomes cheaper due to economies of scale, increased experience with efficiency measures or other factors. To support its assumption, the EPA relies on a single study that actually rejects the EPA's interpretation, stating, "These findings *cast doubt* on the hypothesis that programs with higher electricity savings levels are associated with higher CSE [cost of saved energy] values."<sup>21</sup> In short, EPA's cost estimates for efficiency are—as the EPA stated multiple times in its proposal—"notably conservative."<sup>22</sup> New Hampshire will likely make efficiency gains at much lower cost than the EPA projects, which means even greater savings for electricity customers.

## Conclusion

The Clean Power Plan offers New Hampshire a great opportunity not just to curb climate change, but to lower electricity bills. We project that if the state follows the possible course envisioned by the EPA, then annual electricity bills will fall by 10.3 to 11.5 percent by 2030, which amounts to \$122 to \$136 in annual savings for the average household. These numbers are likely too low, as they incorporate the EPA's admittedly conservative take on energy efficiency. New Hampshire can and should choose to exceed the EPA's expectations. Stronger improvements in energy efficiency will lead to even lower electricity costs for New Hampshire consumers and businesses.

## Methodology

This study relies principally on the EPA’s analysis of its proposed Clean Power Plan. The EPA has proposed two possible sets of state targets, which it calls Option 1 and Option 2, and it envisions that states might comply individually or in regional groups. Therefore, it analyzed four potential scenarios, in which states meet Option 1 or Option 2, individually or regionally. This study considers only Option 1, the stronger of the two sets of targets, but it analyzes both the individual state compliance scenario (termed “State” in charts) and the regional cooperation scenario (termed “Regional” in charts).

*Household consumption.* EPA provides business-as-usual (“BAU”) sales data for the years 2012 through 2040, using 2012 historical data and making projections forward.<sup>23</sup> We use EPA’s BAU sales estimates for the years 2020, 2025 and 2030 as the baseline figures for electricity consumption in New Hampshire. To calculate average household electricity consumption, we begin with EIA data on household electricity consumption in 2013.<sup>24</sup> EIA’s household data does not include projections of future consumption. We develop household BAU values for 2020, 2025 and 2030 by adjusting the 2013 household consumption figure proportionately to the growth in EPA’s aggregate BAU sales data for those periods. In other words, we assume that household electricity consumption will rise or fall at the same rate as general consumption.

To calculate household consumption under the Clean Power Plan, we use the EPA’s projections of New Hampshire’s cumulative energy efficiency savings for each year to modify the estimates for household consumption.<sup>25</sup>

*Household costs.* For each Electricity Market Module (EMM) region, the EPA’s Regulatory Impact Analysis provides an estimate of electricity rates in the base case and under each compliance scenario for the years 2020, 2025 and 2030.<sup>26</sup> New Hampshire is part of the New England region, or NEWE, which also contains Connecticut, Maine, Massachusetts, Rhode Island, and Vermont.<sup>27</sup> The EPA’s analysis treats electricity rates as the same across the region, and this report follows the EPA in that regard. To calculate household costs for each scenario, we multiply our estimate of household consumption by the electricity price that EPA projects.

To calculate the consequences of New Hampshire making stronger improvements in energy efficiency than the EPA projects, we use the earlier start date, higher growth rate and maximum target discussed in the text of this report to perform the calculations that the EPA describes in the technical support document GHG Abatement to arrive at annual cumulative energy efficiency savings.<sup>28</sup> Then we use these cumulative savings figures instead of those in the EPA’s Regulatory Impact Analysis to modify the estimates for household consumption.

The following table contains the numbers represented in this report’s illustrations:

	Rate Impact: State	Rate Impact: Regional	Electric Bill Impact: State	Electric Bill Impact: Regional	Electric Bill Impact: State	Electric Bill Impact: Regional	Electric Bills: Baseline	Electric Bills: CPP State	Electric Bills: CPP Regional
2020	11.6%	10.1%	8.4%	7.0%	\$89.07	\$74.18	\$1,057.19	\$1,146.25	\$1,131.37
2025	2.1%	1.4%	-6.2%	-6.8%	-\$68.18	-\$75.30	\$1,099.81	\$1,031.63	\$1,024.52
2030	1.3%	0.0%	-10.3%	-11.5%	-\$122.36	-\$136.21	\$1,182.40	\$1,060.05	\$1,046.19
