The EPA Clean Power Plan Will Cut Pennsylvania Electricity Bills by 9.2 to 9.8 Percent by 2030
Acknowledgments

This report was written by David Arkush, managing director of Public Citizen's Climate Program. Starla Yeh and Kevin Steinberger of the Natural Resources Defense Council provided helpful input and reviews of the methodology.

About Public Citizen

Public Citizen is a national non-profit organization with more than 400,000 members and supporters. We represent consumer interests through lobbying, litigation, administrative advocacy, research, and public education on a broad range of issues including consumer rights in the marketplace, product safety, financial regulation, worker safety, safe and affordable health care, campaign finance reform and government ethics, fair trade, climate change, and corporate and government accountability.
Introduction

This summer, the Environmental Protection Agency (EPA) expects to finalize its first-ever rule to curb carbon pollution from existing power plants, known as the Clean Power Plan. This report finds that the EPA rule should lower Pennsylvania electricity bills substantially, and that the state can and should do even better.

Detractors often argue that EPA proposal will raise electricity rates. That claim focuses on the wrong question from the standpoint of electricity customers. For a consumer or business focused on costs, the key question is what effect the Clean Power Plan will have on what they actually pay, which means electricity bills. Although the EPA projects that the retail price of electricity will rise modestly under the Clean Power Plan compared to a business-as-usual scenario, it also expects the rule to spur improvements in energy efficiency so that people use less electricity. The net result is that electricity bills will fall, not rise.

The EPA estimates that, in addition to mitigating climate change and boosting public health, the proposed Clean Power Plan will lower electricity bills nationwide by 8.4 percent by 2030 compared to a business-as-usual scenario. The agency did not conduct a state-by-state analysis of bill impacts. For this report, Public Citizen analyzed data from the EPA and the U.S. Energy Information Administration (EIA) to project the Clean Power Plan’s effect on electricity bills in Pennsylvania. We find that by 2030, electricity bills will be 9.2 to 9.8 percent lower under the Clean Power Plan, saving the average Pennsylvania household $125 to $132 annually. Moreover, these numbers are likely underestimates. Pennsylvania can and should do even better. The Clean Power Plan presents a great opportunity for Pennsylvania not just to fight climate change, but to lower electricity costs for consumers.

One important caveat to this report’s analysis is that actual outcomes will depend on Pennsylvania’s policy choices. State officials will decide how to comply with the Clean Power Plan, and they can adopt policies that are better or worse for Pennsylvania’s electricity customers. Energy efficiency should feature prominently in Pennsylvania’s compliance plan, as it is the lowest-cost way to reduce carbon emissions. It also happens to save consumers and businesses a great deal of money on their electricity bills. But the choice lies with Pennsylvania’s policymakers.

The Clean Power Plan Can Lower Electricity Bills in Pennsylvania

The proposed Clean Power Plan aims to cut carbon pollution from power plants by 30 percent from 2005 levels by 2030. Under the plan, the EPA will set a carbon-reduction target for each state, and then states can decide how to meet their targets. They can comply individually or in regional groups, and they can use a mix of different strategies, like improving the efficiency of existing coal-fired power plants, shifting some electricity generation from coal to natural gas plants, shifting to renewables or nuclear generation and using energy efficiency to reduce electricity consumption. Energy efficiency should play a major role in state plans, as it is the lowest-cost and most effective strategy for reducing carbon pollution by a wide margin.
Improving energy efficiency means using less electricity to do the same or more work. For example, better insulated homes require less power to heat and cool. There are many other ways to improve efficiency, ranging from switching to more efficient appliances and light bulbs to using combined heat and power (CHP) systems in industrial processes to generate electricity and usable heat in a combined system rather than independently. Efficiency gains are usually so inexpensive that they pay for themselves quickly in reduced electricity costs. A 2014 study by the American Council for an Energy-Efficient Economy (ACEEE) found that energy efficiency programs run by utilities return $1.41 to $4 for every dollar spent. For this reason, even if the retail price of electricity increases modestly under the Clean Power Plan, households and businesses will use substantially less electricity due to efficiency measures, and their bills will still decline.

Figure 1 illustrates the projected retail electricity rates and total electricity bills in Pennsylvania under the Clean Power Plan, expressed as percentage changes from a business-as-usual baseline. The EPA’s data suggests that the price of electricity will rise initially under the Clean Power Plan but soon fall back toward business-as-usual levels. If Pennsylvania complies individually, then retail rates will be 7.9 percent higher than business-as-usual in 2020, then drop to just 2 percent higher in 2025 and 3.2 percent higher in 2030. If Pennsylvania complies in a regional group, then the EPA’s data suggests that the retail price of electricity will be 8.3 percent higher than business-as-usual in 2020, just 0.6 percent higher in 2025 and 2.6 percent higher in 2030. In either case, our analysis of EPA data suggests that electricity consumption in Pennsylvania will decline by 4.7 percent in 2020, 9.4 percent in 2025, and 12.1 percent in 2030. The net effect, also shown in Figure 1, is that electricity bills will rise modestly in 2020 before declining much more steeply in 2025 and 2030. By 2030, electricity bills will be 9.2 to 9.8 percent lower than they would be without the Clean Power Plan, depending whether the state complies individually or regionally.
Figures 2(a) and 2(b) illustrate the effects of these changes on annual household expenditures, expressed in dollars. We estimate that the average household will see annual electricity bills rise by $35 to $40 in 2020, then decline by $101 to $118 in 2025 and $125 to $132 in 2030 compared to business-as-usual. In other words, the typical household would pay $1,353 for electricity in 2030 without the Clean Power Plan, but would pay $1,221 to $1,228 under the rule.

**Costs Will Likely Decline More Than This Analysis Indicates**

The estimated cost reductions in this report are likely understated. This analysis is based on the compliance option that the EPA proposed for Pennsylvania in the Clean Power Plan, but Pennsylvania has the flexibility and capability to use substantially more efficiency than the EPA envisions. The agency's plan omits entire categories of efficiency measures that states can use, such as building codes and appliance standards. The plan also anticipates that states will improve efficiency by only 1.5 percent annually even though eleven states have already set higher targets.

A recent ACEEE analysis shows one way Pennsylvania could do better on efficiency. It finds that the state could enact a set of energy efficiency policies that by 2030 would save electricity customers $2.7 billion in 2030 alone, as they would use 27,895 fewer gigawatt hours of electricity. This scenario involves a 1.5 percent savings target, like EPA’s, but it adds building codes, combined heat and power, and energy efficiency standards for five products.

A second reason why this report likely underestimates the potential savings under the Clean Power Plan is that it relies on EPA’s excessively high estimates of the cost of efficiency programs. The agency starts its analysis by treating efficiency measures as 60 to 100 percent more expensive than the evidence indicates, using in the EPA’s own words, a “conservative” cost estimate for efficiency programs that is higher than the costs indicated by the “up-to-date, more comprehensive results” from “newer” studies. Then the agency boosts the costs further by assuming that they escalate...
dramatically as the rate of energy efficiency savings increases.\textsuperscript{18} This assumption is no more obvious than the opposite one, that efficiency becomes cheaper due to economies of scale, increased experience with efficiency measures or other factors. To support its assumption, the EPA relies on a single study that actually rejects the EPA’s interpretation, stating, “These findings \textit{cast doubt} on the hypothesis that programs with higher electricity savings levels are associates with higher CSE [cost of saved energy] values.”\textsuperscript{19} In short, EPA’s cost estimates for efficiency are—as the EPA stated multiple times in its proposal—“notably conservative.”\textsuperscript{20} Pennsylvania will likely make efficiency gains at much lower cost than the EPA projects, which means even greater savings for electricity customers.

**Conclusion**

The Clean Power Plan offers Pennsylvania a great opportunity not just to curb climate change, but to lower electricity bills. We project that if the state follows the possible course envisioned by the EPA, then annual electricity bills will fall by 9.2 to 9.8 percent by 2030, which amounts to $125 to $132 in annual savings for the average household. These numbers are likely too low, as they incorporate the EPA’s admittedly conservative take on energy efficiency. Pennsylvania can and should choose to exceed the EPA’s expectations. Stronger improvements in energy efficiency will lead to even lower electricity costs for Pennsylvania consumers and businesses.
Methodology

This study relies principally on the EPA's analysis of its proposed Clean Power Plan. The EPA has proposed two possible sets of state targets, which it calls Option 1 and Option 2, and it envisions that states might comply individually or in regional groups. Therefore, it analyzed four potential scenarios, in which states meet Option 1 or Option 2, individually or regionally. This study considers only Option 1, the stronger of the two sets of targets, but it analyzes both the individual state compliance scenario (termed “State” in charts) and the regional cooperation scenario (termed “Regional” in charts).

Household consumption. EPA provides business-as-usual (“BAU”) sales data for the years 2012 through 2040, using 2012 historical data and making projections forward.21 We use EPA’s BAU sales estimates for the years 2020, 2025 and 2030 as the baseline figures for electricity consumption in Pennsylvania. To calculate average household electricity consumption, we begin with EIA data on household electricity consumption in 2013.22 EIA’s household data does not include projections of future consumption. We develop household BAU values for 2020, 2025 and 2030 by adjusting the 2013 household consumption figure proportionately to the growth in EPA’s aggregate BAU sales data for those periods. In other words, we assume that household electricity consumption will rise or fall at the same rate as general consumption.

To calculate household consumption under the Clean Power Plan, we use the EPA’s projections of Pennsylvania’s cumulative energy efficiency savings for each year to modify the estimates for household consumption.23

Household costs. For each Electricity Market Module (EMM) region, the EPA’s Regulatory Impact Analysis provides an estimate of electricity rates in the base case and under each compliance scenario for the years 2020, 2025 and 2030.24 Most of Pennsylvania is in a region called Reliability First Corporation East, or RFCW. Pittsburgh and some other parts of western Pennsylvania are in Reliability First Corporation West, or RFCW, which also contains Indiana, Ohio, West Virginia, and parts of Illinois, Michigan, Virginia, and Wisconsin.25 One Pennsylvania county, Pike County, is in a New York region, NYUP. Within a given region, the EPA’s analysis treats electricity rates as the same across that region, and this report follows the EPA in that regard.

To calculate average rates for Pennsylvania as a whole, we weight each region’s rate projection by its proportion of state electricity sales on the EIA’s 2012 form 861 (this is the sales data that the EPA uses).26 RFCE accounts for 72.1 percent of sales, while RFCW accounts for 27.9 percent and NYUP just 0.1 percent. To calculate household costs for each scenario, we multiply our estimate of household consumption by these projected electricity rates.
